## **EXECUTIVE SUMMARY**

The purpose of this project was to estimate the volume of water that was expected to be used by agriculture in Pennsylvania on irrigated onto plant production units and used by animal production units in the years 2002 and projected to be used in 2010, 2020, and 2030. It was assumed that the growing seasons (March to October) of 2010, 2020, and 2030 will have 10-year return period droughts.

The number of irrigated acres of for each crop was taken from the United States Department of Commerce National Agricultural Statistics Service (NASS) for the years of 1982, 1987, 1992, 1997, and 2002. Total irrigated crop acreages were collected as well as irrigated acreages in corn (for grain and silage), vegetables, orchards, and berries. The irrigated crop acreages were summarized for each county, plotted as a function of year and extrapolated to 2010, 2020, and 2030 using multiple linear regression with year of interest and growing season rainfall deficit as independent variables (Appendix C). The estimated maximum 7-day water needed for irrigation in each county and for each crop are presented in Chapter 5 with additional details in Appendix D. Based on this analysis, the maximum daily ( $Q_{7-10}$ ) water needed for Pennsylvania was about 140 MGD for all crops in 2002; a year with a 1.2- to 1.8-year drought. Under the assumption that 2010, 2020, and 2030 would experience a 10-year drought, 245, 304, and 360 MGD, respectively will be needed to meet the  $Q_{7-10}$  requirement in each of these years.

An annual analysis of irrigation water needs was also completed, which showed that about 11,300 MG of water was used for irrigating crops in 2002, which had a drought return period of between 1.2 and 1.8 years. Under the assumption that 2010, 2020, and 2030 would experience a 10-year drought, 22,500, 27,900, and 33,300 MG, will be needed for irrigating crops in each of these years, respectively, see Chapter 6 and Appendix E for details.

The animal populations were taken from the United States Department of Commerce NASS for the years 1982, 1987, 1992, 1997 and 2002. The animals taken into consideration for this study were cattle (milk, adult cows, and young cattle), poultry (young birds, layers, broilers, and turkeys), swine, sheep, goats, and horses. Within each county, the populations of each animal were plotted as a function of year and extrapolated to 2010, 2020, and 2030 using a straight-line extension of the 20 years of available data. These estimated animal populations and resulting water needed for each species are presented in Chapter 9 with additional details in Appendix F. Based on this analysis, about 48 MGD of water was used for raising animals in 2002. Animal water use is expected to require 49, 50, and 51 MGD for 2010, 2020, and 2030, respectively.

Using these irrigated cropland and animal estimates, the maximum daily water requirement for agriculture in 2002 was 188 MGD. In 2010, 2020, and 2030 assuming a 10-year drought occurs in each of these years, agriculture is expected to have a maximum daily water requirement of 294, 354, and 414 MGD, respectively, see Chapter 10.

Finally, estimates were made of how much agricultural water was already registered in comparison to how much should have been registered in each county, see Chapter 12. When the monthly registration data was used to identify registered irrigation and animal water, there was considerable water that could be identified as un-registered. When the total registered volumes were compared to the water needed in each county for all agricultural water use, there was actually more water registered than is expected to be needed by agriculture.

### Scope of Work

The goal of this project was to estimate the maximum quantity of water used by both animal production units and irrigated on to plant production units within the Commonwealth of Pennsylvania. The irrigation water needed for plant production units to supplement natural rainfall with irrigation will be based on a 10-year drought when producers are most likely to irrigate at a level that will stress the available water resources of the Commonwealth. Total water needed for agriculture, both for crop irrigation and animal production, was developed from the Ag Census/Ag Statistics data (National Ag Statistics Service (NASS)). If practical, the estimates reported will be based on water used by production units large enough to require more than 10,000 gpd. The study focused on the 2002 NASS data, which was the latest available data available. NASS data from 1982, 1987, 1992, and 1997 were used to establish trends in crop acreages irrigated and animal populations, which were used to extrapolate agricultural water use to 2010, 2020, and 2030. PADEP also supplied partial results from the agricultural water registration program. These data were available to verify and it was hoped that these data could be used to establish how many farmers in each county should have registered. The hope was that with a record of those who had registered and how much water was needed in total by agriculture, those farmers who had not registered, and should have, would be identified. This was impossible from the data supplied. It was also hoped that it might be possible to identify how much of the water used by agricultural production units was being used on farms large enough to use more than 10,000 gpd; thus needing to register their water use. There was nothing in the NASS data source or the registration data supplied by PADEP to make this extrapolation of the water use data. The water use data for the current (2002) results and the predictions of how much water will be needed in the future were delineated into the monthly and annual animal and plant irrigation water use needed in each county. Summarization of the county results to include the three major watersheds (Ohio, Susquehanna, and Delaware) and other smaller watersheds will be the responsibility of PADEP.

Estimates of maximum agricultural water use for the years 2010, 2020, and 2030 were evaluated on a county-by-county basis. These estimates specifically delineate the water needed for both animal and irrigated crop agriculture and are presented on a monthly, annual and county basis.

Estimating Crop Irrigation Water Use: Irrigated crop acreages were available from NASS, which published summaries every five years. The crops that are most often irrigated in Pennsylvania are small fruits, turfgrasses, tree fruits (apples and peaches), vegetables, potatoes and corn. Turfgrasses will not be included in this study. The acreages taken from the NASS data and extrapolated into the future were multiplied times the water-needed results from the PA-DER (1978) study to convert crop acreages grown in Pennsylvania to equivalent depths of water needed for irrigation in Pennsylvania. The influence on irrigated crop acreages by the local climatological data (USDC, 1974) resulted in excellent extrapolations to determine the irrigated acreages in 2010, 2020, and 2030.

These results were summarized to determine the annual irrigated water needed during each month during a 10-year drought. These monthly water use values were then summarized for each major crop, each month of the growing season, and within each county.

Estimating Animal Water Use: Animal populations for each county within the state are available from the NASS, which are published every five years. The county-wide animal populations for cattle, swine and poultry as well as horse, goats and sheep were collected from data published since 1980. The latest census data will form the basis for estimating the current agricultural animal water needs within each county. These animal populations were extrapolated to yield animal populations in 2010, 2020, and 2030. Using the extrapolated animal populations, the average water intake (by drinking) for each animal will be applied to compute total animal water use in 2002 (the current use level), 2010, 2020, and 2030.

# PART I

Irrigation Water Assessment

### **Irrigation Water Needs Assessment**

The irrigation water needs assessment consisted of three parts; (1) estimate the present annual and  $Q_{7-10}$  irrigation water needs for each County based on the most recent (2002) irrigated acreages available, (2) extrapolate the historical (1982, 1987, 1992, 1997, and 2002) irrigated acreages to predict the 2010, 2020, and 2030 annual and  $Q_{7-10}$  irrigation water needs in each County, and (3) attempt to estimate what portion of the irrigating farmers in each County who have already registered (or have not registered) their water use with PADEP. The present (part 1) and extrapolated (part 2) irrigation water needs assessment for each County and the state are contained in the EXCEL spreadsheet named "Irrigation Projection Analysis\*.xls" found on the CD in the rear pocket. The sheets named "Soils Data", Weather", "Basel", and "Irrig" contain the data and the various analyses performed. The results of the irrigation and animal water need results are also combined and summarized into a separate spreadsheets named "Water Results\*.xls", which are also on the Report CD. The "\*" in the name of each spreadsheet mentioned above refers to the first letter of the counties included in each spreadsheet. The spreadsheets that include the number "7" contain the Q<sub>7-10</sub> analyses.

The registration analysis (part 3) for each County and the state is contained in the EXCEL spreadsheet named "Registration Analysis". The sheets named "Soil Data", "Weather", "Reg"istration, "Basel", and "Irrig" contain the data and the various analyses performed. Again the results are summarized on a sheet named "Summary".

Acreages of irrigated land in each county were available for several crops. The acreages of corn (for grain + for greenchop or silage), all vegetables, orchards, berries and the total irrigated acreage for each county were taken from the NASS data base. Unidentified irrigated acreages (total - corn - vegetables - orchards - berries) were then calculated and identified as "unknown crops". One of the difficulties with trying to use NASS data was that NASS is careful to protect the reporting farmers from identification. Therefore, when a county had only a one, or a few, reporting farmers in a crop category, NASS reports how many farmers reported irrigated acreage in that crop, but they will not identify how many acres were irrigated. For instance, under acres of corn for grain irrigated in Adams County in 1987, there were only 2 farmers reporting irrigated corn. Therefore, NASS reported that "2" farmers irrigated corn, but because it might be possible for a local person to figure out which specific farmers these two farmers might be, NASS did not report the total acres of corn these two farmers irrigated; instead they simply report the acreage as "(D)". These holes in the data sets caused some concern during this analysis because on the one hand it is misleading to report the "(D)" as zero acres irrigated, but it is also impossible to know how many acres were actually irrigated. This problem was solved by artificially inserting a number into the analysis. These numbers varied with the different crops irrigated. In the case of berries, we assumed a "(D)" was equal to 2 acres/farm. In the case of most other crops the "(D)" was assumed to be 5 acres. If you look at the specific data in the spreadsheets, these estimated values are evident because they are rounded to 1 or 2 significant figures while the actual NASS data are reported to the last acre.

#### **Present Irrigation Water Volume**

The present irrigation water needs in each County were estimated from the irrigated acreages reported in NASS (2002). The NASS irrigated crop acreages were multiplied times the monthly irrigation water depths needed in each County on a annual or  $Q_{7-10}$  basis (Chapter 3) to determine the volume of water needed for irrigation in each County under the present circumstances. These data are in attached EXCEL spreadsheet named "Irrigation Projection Analysis" in sheet "Irrig" and summarized in sheet "Summary".

#### **Extrapolated Future Irrigated Water Volume**

The extrapolated irrigated acreage predictions for 2010, 2020, and 2030 were based on a linear equation fit to the historical irrigated acreages from 1982, 1987, 1992, and 1997 (NASS, 1982, 1987, 1992, 1997) and the irrigated crop acreages for 2002 used to determine the present water needs to produce the minimum sum of squares between the actual and predicted acreages.

The procedure for extrapolating the historical irrigated acreages between 1982 and 2002 to predict the irrigated acreages expected in the future years of 2010, 2020, and 2030 required that we identify one or more parameters that were expected to influence a grower's decision to either purchase or put-into-use an irrigation system. The two most important parameters were (1) the years of interest (1982, 1987, 1992, 1997, 2002, 2010, 2020, and 2030) and (2) the precipitation deficit for each growing season. For the historical years in the analysis, the

actual growing season precipitation deficits were used. For the extrapolated years (2010, 2020, and 2030) the precipitation deficit expected during a 10-year return period drought in that region of Pennsylvania was used.

Effect of Year. The correlation to the year of interest, Y is essentially the understanding that if we look at acres irrigated in 2002 and compare these with acres irrigated during any earlier year, the more recent year will have more irrigators (or acres irrigated). Growers tend to adopt irrigation technology with time and when they are faced with a particularly dry growing season (when crops are essentially lost to drought) they may be stimulated to purchase an irrigation system. Once purchased, this grower will have a tendency to use his/her irrigation system, especially during years when rainfall is below normal.

For purposes of developing an equation that could be used to extrapolate irrigated acreages into the future years an equation of the form.

$$A(Y) = a_1 Y^{b_1} + c_1 \tag{1}$$

Where A is the acres irrigated in year Y,  $a_1$  is the slope of the best fit line,  $b_1$  is the exponent and  $c_1$  is the intercept where this best fit line crosses year zero.

Effect of Precipitation Deficit. The other strongly correlated parameter was the precipitation deficit that occurred during each growing season. Precipitation deficits were developed from the Pennsylvania climatological data summaries as described in Chapter 4. For purposes of developing an equation that could be used to extrapolate irrigation acreages into the future years, the acreages were related to the precipitation deficits, D as

$$A(Y) = a_2 D(Y)^{b_2} + c_2$$
(2)

Where A is the acres irrigated in year Y,  $a_2$  is the slope of the best fit line,  $b_2$  is the exponent and  $c_2$  is the intercept where this best fit line crosses the zero deficit. By adding equations 1 and 2 the following predictive equation is formed.

$$A(Y) = a_1 Y^{b_1} + a_2 D(Y)^{b_2} + c_1 + c_2.$$
 (3)

Since  $c_1$  and  $c_2$  are constant intercept coefficients, they can be replaced with a single coefficient, Const =  $c_1 + c_2$ . When  $b_1$  and  $b_2$  were set equal to 1 (unity), as they were in these evaluations, equation 3 is a linear multiple regression equation. Thus, the extrapolation equation fit to each crop in each county to determine the irrigated acreages expected in 2010, 2020, and 2030 was:

$$A(Y) = a_1 Y + a_2 D(Y) + Const$$
<sup>(4)</sup>

Various  $a_{1,} a_{2}$  and Const coefficients were tried using the "Solver" routine in EXCEL to determine the set of coefficients that yielded the minimum sum of squares,  $S_{min}$  where  $S_{min}$  was defined as:

$$S_{\min} = \sum_{1}^{n} (A(Y) - A_{a}(Y))^{2}$$
(5)

Where  $A_a(Y)$  is the actual acres irrigated in each of the years for which NASS irrigated acreages were available between 1982 and 2002 and the predicted acreages for 2010, 2020, and 2030 (n = 8). This extrapolation procedure was applied to five crops or crop categories in each County. These crops or crop categories were Total Land Irrigated, Corn (total of corn for grain and corn for greenchop), Orchards, All Vegetables, and Berries. The results of each extrapolation are shown with the irrigation data (sheet "Irrig") in the attached "Irrigation Prediction Analysis\*.xls" spreadsheets. The acreages predicted to be irrigated were assumed to be the same whether the subsequent analysis was for the annual or  $Q_{7-10}$  assessment.

#### **Assessment of Present Registrations**

Included in NASS (2002) are data that tell how many acres of land is under irrigation in each County based on the size of the farm. These data were used to determine the average number of acres of land irrigated on each size of farm. By knowing how much water is likely to be used for irrigation in each County, we could determine approximately how many acres of irrigated land would be needed before the farmer probably used more than the 10,000 gpd trigger volume required for registration. PADEP also supplied the results of the individual farmer water registrations. By making several reasonable assumptions we were able to estimate each of the following parameters for each County:

- Total number of farms irrigating.
- Number of farms irrigating a large enough acreage to require registration based on the 10,000 gpd registration limitation.

- Number of irrigating farms that already registered.
- Total water needed for irrigation in MG.
- Total irrigation water registered in MG.

These results are located in the "Irrig" sheet of the attached "Registration Analysis" spreadsheet and summarized in the sheet named "Summary". These results are summarized in Chapter 12.

## Irrigation Needs for Each Crop

### Pennsylvania Irrigation Water Requirement Reports

Many published reports provide information about Pennsylvania's irrigation water requirements. The most important of these are summarized and evaluated below.

**1955 Pennsylvania Guide for Sprinkler Irrigation Design.** The earliest known report was the Pennsylvania Guide for Sprinkler Irrigation Design (SCS et al., 1955). This Guide was developed by SCS personnel and was written for SCS Farm Planners. This report pointed out the need for good soil and crop management as well as the need for a good water supply. It also identified the major components of a good sprinkler irrigation system and its design. It then divided all Pennsylvania soils into 11 Irrigation Soil Groups and delineated maximum application rate, a wide variety of crops to be considered, their rooting depths and respective available moisture capacities plus each crop's design depth (depth of irrigation water to be applied during each irrigation application), irrigation interval (how many days there should be between irrigation applications) and consumptive use. Finally several graphs were given to help farmers and planners know what maximum volume of irrigation water may be needed over a 30-day drought period based on selected pumping rates. No attempt was made to estimate how often irrigation might be needed or what impact natural precipitation might have on total irrigation water needs. They did indicate that tree fruits, commercial vegetables, truck crops, cabbage, potatoes and improved pastures usually paid the highest cash return for the irrigation system capital invested.

**Estimates of Supplemental Water Needed by Forage Crops in Pennsylvania.** Dailey et al. (1960) used climatological data from 36 Pennsylvania weather stations covering the 32-year period from 1925 to 1956 to determine the depth of irrigation water needed to grow forages in Pennsylvania. Their soil moisture simulations were based on the following assumptions:

- That forage crops do not need supplemental water before May or after September.
- That 3.0, 3.5, 4.0 and 4.5 inches of available moisture in the root zone at field capacity would cover most irrigable soils in PA.
- That all soils were at field capacity on May 1 of each year.
- That 0.2 inches of water per day would be applied by the irrigation system. This 0.2 inches was assumed to include a safety factor that covered the system losses and the daily evapotranspiration.
- That supplemental water was not applied on days when total rainfall exceeded 0.2 inches.
- If rain raised the moisture content in the root zone above field capacity, the remainder of the rain was considered lost from the plant-growth system.

Their soil water budget was simulated using 55% of the available water as the "trigger" to start irrigation and irrigation was stopped when the root zone moisture content reached field capacity.

The results from this study were intended to aid in the design and management of irrigation systems and did not provide data that helped extrapolate irrigation needs into the future under excessive drought conditions.

**Soil-Plant-Water Relationships as a Basis for Irrigation: Crop Response to Irrigation in the Northeast.** Vittum et al. (1963) reported the crop yield responses resulting from many different irrigation trials on a wide variety of crops in the northeast U.S. during the period 1949 to 1960. A wide variety of "triggers" were tried including 25, 40, 50, and 75 % of the capillary depletion, once a week, and every 10 days. There was a significant crop yield increase when snap and lima beans received 1.5 to 3.0 inches of irrigation water per season. There was a significant crop yield increase when cabbage received 0.8 to 12.1 inches of irrigation water per season in Connecticut and New Jersey, but not in New York. There was a significant crop yield increase when potatoes received 1.5 to 11.3 inches of irrigation water per season. Sweet corn did not generally respond to irrigation, even when 1.8 to 6.5 inches of irrigation was applied during the growing season, but it did respond to larger amounts of water. In general tomatoes did not respond to irrigation. Like sweet corn, forage crops did not generally respond to irrigation unless very large depths (10 to 15 inches) of water were applied. **1972 Pennsylvania Irrigation Guide.** USDA-SCS (1972) re-released the 1955 Pennsylvania Irrigation Guide. This time the soils were divided into 10 Irrigation Groups, with available moisture capacities delineated as a function of rooting depth. In addition to providing guidance on how to design an efficient sprinkler irrigation system, they delineated the monthly and annual depths of irrigation water that should be needed for apples, peaches, potatoes, sweet corn, tomatoes, small vegetables, and strawberries/small fruits during normal and dry years. No data sources or methodologies were given. Thus no explanation was given of how these irrigation requirements were derived. The authors believe these values are rather reliable and consistent with actual irrigation depths needed during Pennsylvania growing seasons. In addition, the guide provided a listing of Critical Periods of Water Needs for various crops.

Analysis of Water Requirements for Agricultural Irrigation in Pennsylvania. In 1977, PA-DER funded an extensive study designed to estimate irrigation water requirements for Pennsylvania agriculture (Kibler et al, 1977). This was a massive study that first identified the crops most likely to be irrigated in Pennsylvania along with each crop's growing season and rooting depth. It then identified the water-related soil characteristics for soils most likely to be irrigated in Pennsylvania. It included stream flow data for 30 small Pennsylvania watersheds and meteorological data for 65 Pennsylvania weather stations during the period 1948 to 1975, thus effective precipitation could be evaluated. It evaluated ET and then developed a daily soil moisture budget for each soil, each crop's rooting zone, and each geographic location to predict how much irrigation water would be needed as a function of 1.01-, 2-, 10- and 50-year drought return periods. They applied total seasonal, 7-, 14-, and 28-day water stress periods and determined the depths of irrigation water needed in each location as a function of crop rooting depth and hardiness. The results of this study were presented as the irrigation water needed to keep root-zone water levels within the optimum plant-growth limits during each of four sub-seasons (3/1-5/2) (5/3-7/4) (7/5-9/5) (9/6-11/7). These four sub-seasons encompassed the entire Pennsylvania cropgrowing season. The study simulation model applied irrigation water when the root zone moisture content declined to 50% of root-zone available-water-capacity; This root-zone water-content is often called the irrigation "trigger" point; the root-zone water-content when irrigation should be initiated to keep the growing crops from experiencing water stress. On those occasions when irrigation water was needed (root-zone water-content reached the "trigger" point), the depth of water irrigated was the depth of water needed to bring the crop's root zone moisture content to field capacity. These irrigation depths were summed for the crop's entire growing season. These irrigation depths were then summarized by location, each of the four sub-seasons, each crop and for the drought return periods of 1.01, 2, 10 and 50 years assessed for periods of 7-, 14-, and 28-day precipitation amounts. This was a comprehensive study that produced reliable estimates of irrigation water needs in Pennsylvania and is as close to a comprehensive study of Pennsylvania irrigation needs as exists. The 7-day, 10year return period results from this study are the basis for the Q<sub>7-10</sub> analysis reported herein.

**Pennsylvania Irrigation Water Application: Planning and Management Guide.** This PA-DER (1978) report is a summary of the irrigation water depth needed for the 1.01, 2, 10, and 50 year return periods extracted from the Kibler et al. (1977) study. The heart of this report is Table 2, which contains two sub-sections; one titled "Total Season Deficits" and a second titled "Maximum 28-Day Amounts". The Maximum 28-Day Amounts were copied directly from Table 12-3 of Kibler et al. (1977). The Total Season Deficits were proportionally adjusted from the Maximum 28-Day Amounts based on the total seasonal deficits computed at 12 selected locations across Pennsylvania, see Chapter 12 of Kibler et al. (1977). These Total Seasonal Deficits (see Appendix A) copied from PA-DER (1978) are the best-documented and most reliable total-season drought return-period based measures of irrigation water needs in Pennsylvania.

**Hydro-Economic Analysis and Projection of Irrigation Water Demands in Pennsylvania.** In 1981, PA-DER funded a second extensive study (Kibler et al., 1981) that attempted to relate Pennsylvania irrigation water use requirements to the economic climate of Pennsylvania's agriculture. Their intent was to assess how much of the upper bound irrigation based consumptive use water identified by Kibler et al. (1977) and copied into the PA-DER (1978) report was expected to be used by agriculture on an economical basis.

The major finding of this investigation was that irrigation of moderate value cash crops, such as potatoes, is economically justified in Pennsylvania provided the water can be applied near the optimal water-stress point of the crop. Net returns are maximized when crops are irrigated by means of hand-move, portable-set irrigation systems operated at a "trigger" point of 60% of the available moisture content.

They also developed an estimate of the maximum acreage that could be irrigated under optimum conditions without depleting the available water supplies below the 2-year, 30-day ( $Q_{30-2}$ ) drought level. These upper bound values far exceed the irrigated acreages in Pennsylvania.

The results, reported by Kibler, et al. (1981), were developed entirely from ET and soil moisture data. There was no mention of crop yield reductions from other effects such as high or low temperatures, frost, insect damage, storm damage, field losses etc. In addition they spent a great deal of time considering the "trigger" point, the soil moisture level when irrigation is best initiated and the depth of water that should be applied each time one irrigates. They also indicated that these decisions influence the size of the irrigation system's pumps and pipes and therefore the overall cost of the system. In addition, the capital costs for irrigation are more a function of the actual application time a farmer sets aside for applying water than the "trigger" point. The bottom line is that we believe some of the assumptions behind the water stress index developed in this study are flawed and do not necessarily reflect real farm conditions or how irrigation decisions are made by real farmers.

One last concern we see in the Kibler et al. (1981) report results is in the potential availability of water for irrigation. This analysis assumed that all irrigated waters would come from surface water (streams). Therefore only lands in relative close proximity to existing streams were considered as potential irrigable lands. Historically, Pennsylvania farmers collect surface runoff or spring flows in ponds, pump irrigation water from streams or pump waters from ground water aquifers for irrigation. Two of these three sources can be, and often are, located great distances from flowing streams.

#### Irrigation Water Depth Data Selection Example

In order to show in detail how the irrigation water depth data was selected for this assessment, the following example will be used:

**The example** is to estimate of the quantity of water needed to grow potatoes. Potatoes were chosen for this example because they are one of the important crops irrigated in Pennsylvania. Potatoes are normally assumed to have a rooting depth of about 18 inches. The SCS Irrigation Soil Group #1 in Pennsylvania was selected because this analysis requires specific soil information; a SCS Group #1 soil should have the ability to store about 3.5 inches of water between field capacity and the wilting point in the potato's 18-inch root zone. Standard irrigation operating practice of (1) starting each irrigation application when 50% of the available moisture capacity has been used by the crop, and (2) irrigating until the soil moisture has been raised to field capacity was assumed. How this assumption is actually applied by an irrigating farmer is open to a great deal of interpretation. Farmers equipped to irrigate usually initiate irrigation when their crop begins to show signs of water stress. How much water they will apply (or how long they will let the irrigation system run before shutting it off) usually depends on what they have been told by an extension specialist, some other knowledgeable person, or their own judgment. Snyder County was randomly chosen as the Pennsylvania location.

#### Selection of Best Irrigation Water Depth Data for the $Q_{7-10}$ Analysis

This section shows how the data presented in the reports reviewed earlier in this chapter can best be used to estimate the  $Q_{7-10}$  irrigation water needs in Pennsylvania.

**Kibler, et al. (1977) Results**. Kibler, et al. (1977) presented their total and seasonal soil moisture deficits in terms of the crop's hardiness (hardy, moderate, tender) and the crop's rooting depth. In our example, potatoes are considered to be "moderately" hardy and, as stated earlier, they have an 18-inch root depth. Thus for Snyder County, Table 3-1 summarizes the moisture deficits expected every 1.01, 2, 10, and 50 years for the 7-day analysis period.

These results are somewhat different from what most irrigation engineers are used to seeing. Kibler, et al. (1977) divided the growing season into four sub-seasons of nine weeks each. Their deficits represent the maximum depth of water the potatoes will need during any 7-day drought period within each of the four sub-seasons.

Therefore, by looking at these 7-day maximum deficits (see Appendix A), the maximum water needed for irrigation should be 0.88, 2.17, 3.46, and 4.58 inches for the 1.01-, 2-, 10-, and 50-year drought return periods, respectively. Since our analysis is focused on the 10-year return period, it is reasonable to expect a maximum 7- day irrigation water need of 3.46 inches to occur once every 10 years, most probably during the period from July 5<sup>th</sup> to September 6<sup>th</sup>.

	Tota	hes)			
Drought Return Period (Years)	Mar 1 to May 2	May 3 to July 4	July 5 to Sept 6	Sept 7 to Nov 7	Maximum 7- Day Deficit (Inches)
1.01	0.05	0.66	0.88	0.67	0.88
2	0.15	1.55	2.17	1.30	2.17
10	0.25	1.91	3.46	1.94	3.46
50	0.32	2.03	4.58	2.49	4.58

Table 3-1. Maximum Soil Moisture Deficits For 7-Day Analysis PeriodsPredicted by Kibler, et al. (1977).

It is clear from Kibler et al.'s (1977) documentation that these results are the depth of water that needs to be placed into the root zone to be used by the growing potatoes. Under normal irrigation practice, these irrigation depths need to be increased, by 30% for sprinkler irrigation and 5 to 10% for drip irrigation, to ensure that the total water needed by the potatoes reach the root zone. The extra water applied is expected to be lost to runoff, evaporation, deep percolation, etc. The design depths, from Table 3-1 should be considered consumptive use. The total depth a farmer would apply contains both consumptively used and non-consumptively used water.

#### **Recommended Procedure**

To generate estimates of the Q<sub>7-10</sub> depths of irrigation water needed for Pennsylvania agriculture, we recommend using the 7-day water deficit results from Kibler et al. (1977) and exemplified in Table 3-1 for our example to convert crop acreages grown in Pennsylvania to equivalent maximum 7-day volumes of water needed for irrigation in Pennsylvania. Each PA County's crop acreage-data will be collected. Crop acreages are available for each County 1982, 1987, 1992, 1997, and 2002 from the US Department of Commerce, United State Census of Agriculture (Ag Census, NASS).

After the acreages of each crop have been determined from the best available data, these irrigated crop acreages will be summed within each county and appropriate climatological data (see Chapter 4) will be regressed to yield a relationship that extrapolates the irrigated acreages to the years 2010, 2020 and 2030.

Once the 2010, 2020 and 2030 irrigated crop acreages have been estimated and the best available crop and rooting depth data assessed, the maximum 10-year return period irrigation water needs data for each county will be used, with the projected crop acreages to determine the maximum volumes of water needed in Pennsylvania for irrigation.

The Kibler et al. (1977) data are presented for four growing sub-seasons defined as March 1 to May 2, May 3 to July 4, July 5 to September 6, and September 7 to November 7. In order to determine expected 10-year drought return period water use values on the desired monthly basis, it was necessary to parse the available sub-seasonal results into values for each individual month. This was done by assigning a percentage of each sub-season's water needed depth to each of the months in that sub-season. Table 3-2 shows how these values were divided for each sub-season using the 10-year drought return period data from Snyder County shown in Table 3-1. The 10-year drought return period water use values from Table 3-1 are summarized into the first two columns of Table 3-2. The fourth column shows, by percentage how each of the sub-seasonal water needed depths were assigned to each month in that sub-season. For instance, the first sub-season, from March 1 to May 2, is expected to need 0.25 inches of irrigation water during a 7-day period once every 10 years to keep the potatoes from experiencing water stress. This 0.25 inches of irrigation was assigned to the months of March and April by assuming 20% would be needed in March and 80% would be needed in April. Likewise in the third sub-season, the 3.46 inches of irrigation water needed for July 5 to Sept 6, was divided equally (50% and 50%) to yield 1.73 inches in July and August.

Kibler et al. (1977) Sub-Season	10-Year Sub- Seasonal Water Need (Inches)	Individual Months	How Each Sub- Season was Divided by Percentage (%)	10-Year Water Need Assigned to Each Month (Inches)
March 1 to	0.25	March	20	0.05
May 2		April	80	0.20
May 3 to	1.91	Мау	40	0.76
July 4		June	60	1.15
July 5 to	3.46	July	50	1.73
Sept 6		August	50	1.73
Sept 7 to	1.94	September	70	1.36
Nov 7		October	30	0.58
			Maximum =	1.73

Table 3-2. Percentages of Kibler et al. (1977) 7-day, 10-year Drought Return PeriodSub-Seasonal Water Need Assigned to Each Month.

#### Selection of Best Irrigation Water Depth Data for the Annual Analysis

This section shows how the data presented in the reports reviewed earlier in this chapter might best be used to estimate annual irrigation water needs in Pennsylvania. The potato example will be used here as well.

**Dailey et al. (1960) Results.** If we look at Dailey, et al. (1960), for a rooting zone holding 3.5 inches of available water, their results show that we can expect to apply 10.0 inches of irrigation water 3 years out of any 10-year period. The other return period results are given in Table 3-3. One also needs to note that these results were for the entire northeast U.S. and for forages.

Irrigation Needed (Inches)	Return Period
10.0	3/10
8.5	5/10
7.1	7/10

Table 3-3. Summary of Dailey, et at. (1960) Irrigation Application Results.

It must also be noted that this study was based on a daily application of irrigation water equivalent to 0.2 inches/day when soil moisture conditions were dry enough to stress the crops. The authors also indicate that this 0.2 inches/day of water includes a safety factor because the actual daily ET rate during the normal growing season is usually somewhat less than 0.2 inches/day. They never mention the water application efficiency (WAE), but this is the parameter used by irrigation designers to account for system losses via:

- Evaporation into the atmosphere,
- Runoff due to applying the water faster than the soil's infiltration rate,
- Deep percolation due to over irrigation, and
- System losses due to leakage.

For a well designed and managed sprinkler irrigation system, the WAE is usually about 70%. That means that 70% of the water taken from the source is expected to reach its target of the crop's root zone. Conversely, this assumes that 30% of the water taken from the source will be lost in the sense that it will never reach the crop's root zone.

Therefore, from the results presented in Table 3-3, one should assume that in the 3 out of 10-year drought only 70% of the 10.0 inches, or 7.0 inches, will actually reach its target (the root zone) and be available

for crop uptake. In 5 out of 10 and 7 out of 10 years, the plant uptake is estimated to be 6.0 and 4.9 inches, respectively.

**USDA-SCS (1972) Results.** If we try to analyze this example using the 1972 Pennsylvania Irrigation Guide, we must first decide whether the growing season is "normal" or "dry". There is no guidance given by USDA-SCS (1972) to assist the user in determining whether a season is normal or dry. Based on how Kibler, et al. (1977) and others seemed to define a dry year, we assumed the dry growing season to be one in which there was at least a 2-year return period drought.

A summary of the depths of irrigation water needed to satisfy a crop of potatoes in Snyder County, Pennsylvania for each month of a normal and dry growing season are summarized in Table 3-4.

Month	Normal	Dry
June	0.0	0.2
July	2.0	2.7
August	4.1	4.6
September	3.1	3.6
October	0.3	0.8
Total =	9.5 in	11.9 in

# Table 3-4. Depth of Irrigation Water Needed In aNormal and Dry Year Using USDA-SCS (1972).

The total irrigation needed for the dry year was 11.9 inches. This source also helps in being able to suggest how this irrigation-water need will probably be distributed across the growing season.

The weakness in these results is that USDA-SCS (1972) discusses the impact of the water application efficiency (WAE) on total water to be applied and the design depths given are adjusted for the 70% WAE. The charts that summarize the depth of water to be applied give no hint of whether the WAE was included or not. From using the data in this publication for many years, we are convinced the results presented are the actual depths of water that must reach the crop's root zone and this depth of water will be used by the crop to off-set moisture stress.

It is worth including a note about the critical period included by USDA-SCS (1972). This publication also indicates that potatoes are most sensitive to moisture stress from the "Blossom stage to Harvest". This is the period when it is most important to be sure to try to reduce or eliminate moisture stress.

**Kibler, et al. (1977) Results**. Kibler, et al. (1977) presented their total and seasonal soil moisture deficits in terms of the crop's hardiness (hardy, moderate, tender) and the crop's rooting depth. In our example, potatoes are considered to be "moderately" hardy and, as stated earlier, they have an 18-inch root depth. Thus for Snyder County, Table 3-5 summarizes the moisture deficits expected every 1.01, 2, 10, and 50 years for the 28-day analysis period.

These results are somewhat different from what most irrigation engineers are used to seeing. Kibler, et al. (1977) divided the growing season into four sub-seasons of nine weeks each. Their deficits are given for each of these four sub-seasons, which are added to the right to yield the total growing season deficit.

Therefore, by looking at these 28-day maximum deficits for the total growing season, the water needed for irrigation is 3.7, 11.0, 16.1, and 19.6 inches for the 1.01-, 2-, 10-, and 50-year drought return periods, respectively. Since a dry year was defined earlier as the 2-year return period drought, we expect to need about 11.0 inches of water for this field of potatoes. These 11.0 inches of irrigation water would be needed every other year.

	Tota	Total Sub-Seasonal Deficits (inches)					
Drought Return Period (Years)	Mar 1 to May 2	May 3 to July 4	July 5 to Sept 6	Sept 7 to Nov 7	Growing Season Total (Inches)		
1.01	0.0	0.7	2.8	0.2	3.7		
2	0.2	2.7	6.0	2.1	11.0		
10	0.4	4.4	7.4	3.9	16.1		
50	0.7	5.4	7.9	5.6	19.6		

Table 3-5. Maximum Soil Moisture Deficits For 28-Day Analysis PeriodsPredicted by Kibler, et al. (1977).

It is clear from the documentation given in this report that these results are the depth of water that needs to be placed into the root zone and can be expected to be used by the crop. Under normal irrigation practice, these irrigation depths need to be increased by 30% to ensure that the total water needed by the plants reach the root zone.

**PA-DER (1978) Results.** Following the completion of the Kibler, et al. (1977) report, PA-DER further summarized the Kibler results to yield what they called "Total Seasonal Deficits", see Appendix B. If we again use the Sunbury, Snyder County, PA data for the moderately hardy potatoes with an 18-inch root zone, we can predict the depth of irrigation expected on a drought return period basis as shown in Table 3-6. The format here is the same as Table 3-5 with four sub-seasons that were combined to yield the total seasonal deficit. Again the results are very similar to those of Kibler et al. (1977).

	Tota	hes)	-		
Drought Return Period (Years)	Mar 1 to May 2	May 3 to July 4	July 5 to Sept 6	Sept 7 to Nov 7	Total Seasonal Deficit (Inches)
1.01	0.0	0.5	1.9	0.1	2.5
2	0.2	2.8	6.3	2.2	11.5
10	0.5	4.5	7.7	4.1	16.8
50	0.7	5.3	7.7	5.5	19.2

Table 3-6. Total Seasonal Deficits Predicted by PA-DER (1978).

**Summary Comments.** What this example has shown is encouraging. Of the four studies available to predict the irrigation water needed for potatoes, one gave much lower answers, the other three gave very similar results.

The most difficult result to explain is the 6.0-inch irrigation depth needed to grow forages by Dailey, et al. (1960). It is easy in 2001, to simply indicate that this was old science or technology, but this is unacceptable. The basic procedures used by Dailey, et al. (1960) were essentially the same as the procedures used by Kibler, et al. (1977, 1981). One plausible explanation for the low depth of irrigation given by this study may be that this was a northeast U.S. study and much of the data was from locations further north than PA. It should also be noted that the procedure used by Dailey, et al. (1960) had the poorest documentation of the four studies.

On the other hand the results from USDA-SCS (1972), Kibler, et al. (1977), and PA-DEP (1978) are nearly identical assuming we equate "DRY" in USDA-SCS (1972) with a 2-year drought return period in Kibler, et al. (1977) and PA-DER (1978).

Finally, before we conclude this example, let's compare the results we have assembled for potatoes in Pennsylvania into Table 3-7. It is quite clear from Table 3-7, that there is good agreement between the PA results at the 2-year return period.

Drought Return Period (Years)	Kibler et al. (1977) PA (Inches)	PA-DER (1978) PA (Inches)	USDA-SCS (1972) PA (Inches)
1.01	3.7	2.5	9.5 (Normal)
2	11.0	11.5	11.9 (Dry)
10	16.1	16.8	
50	19.6	19.2	

 Table 3-7. Summary of Irrigation Water Needed to Grow Potatoes

 in Snyder County, Pennsylvania as a Function of Drought Return Period.

In this example the Kibler, et al. (1977) and PA-DER (1978) results were applied to a potato crop. Because of the extensive analysis completed and published by both of these researchers, including results for 43 of the 67 counties in PA and for each of the crops irrigated, these results were brought to this project with very little effort.

#### **Recommended Procedure**

We used the water use results from the PA-DER (1978) study to convert crop acreages grown in Pennsylvania to equivalent depths of water needed for irrigation in Pennsylvania. Each PA County's crop acreage-data will be collected. Crop acreages are available for each County 1982, 1987, 1992, 1997, and 2002 from the US Department of Commerce, United State Census of Agriculture (Ag Census, NASS).

After the acreages of each crop have been determined from the best available data, these irrigated crop acreages will be summed within each county and appropriate climatological data (see Chapter 4) will be regressed to yield a relationship that extrapolates the irrigated acreages to the years 2010, 2020 and 2030.

Once the 2010, 2020 and 2030 irrigated crop acreages have been estimated, the best available crop and rooting depth data, the average 10-year return period irrigation water needs data for each county will be used, with the projected crop acreages to determine volumes of water needed in Pennsylvania for irrigation.

The PA-DER (1978) data are presented for four growing sub-seasons defined as March 1 to May 2, May 3 to July 4, July 5 to September 6, and September 7 to November 7. In order to determine expected 10-year drought return period water use values on the desired monthly basis, it was necessary to parse the available sub-seasonal results into values for each individual month. This was done by assigning a percentage of each sub-season's expected consumptive use to each of the months in that sub-season. Table 3-8 shows how these values were divided for each sub-season using the 10-year drought return period data from Snyder County shown in Table 3-6. The 10-year drought return period water use values from Table 3-6 are summarized into the first two columns of Table 3-8. The fourth column shows, by percentage how each of the PA-DER sub-seasonal consumptive use values were assigned to each month in that sub-season. For instance, the first PA-DER sub-season, from March 1 to May 2, is expected to need 0.5 inches of irrigation water once every 10 years to keep the potatoes from experiencing water stress. This 0.5 inches of irrigation was assigned to the months of March and April by assuming 20% would be needed in March and 80% would be needed in April. Likewise in the third sub-season, the 7.7 inches of irrigation water needed for July 5 to Sept 6, was divided equally (50% and 50%) into July and August. The 3.8 versus 3.9 inches was due to rounding.

PA-DER (1978) Sub-Season	10-Year Sub- Seasonal Water Need (Inches)	Individual Months	How Each Sub- Season was Divided by Percentage (%)	10-Year Water Need Assigned to Each Month (Inches)
March 1 to	0.5	March	20	0.1
May 2		April	80	0.4
May 3 to	4.5	Мау	40	1.8
July 4		June	60	2.7
July 5 to	7.7	July	50	3.8
Sept 6		August	50	3.9
Sept 7 to	4.1	September	70	2.9
Nov 7		October	30	1.2
Total =	16.8			16.8

 Table 3-8. Percentages of PA-DER (1978) 10-year Drought Return Period

 Sub-Seasonal Water Need Assigned to Each Month.

#### Influence of Type of Irrigation System Used

This entire discussion about how much water is needed for Pennsylvania irrigation has been presented under the assumption that irrigation water is applied by a sprinkler system. What does this mean in a practical sense?

The water needs depths shown in the summary tables above for both the  $Q_{7-10}$  (Table 3-2) and annual (Table 3-8) were given as water needed by the crop(s) or water that needs to be placed into the crop root zone so it can be used by the crop in subsequent days or weeks following the irrigation application. Adjustments to these water needs depth can be made in two ways; (1) by looking at the depth of water that an irrigator will need to pump (or take from the water source) in order to make sure they prescribed depths of water actually reach the crop root zones, and (2) how does the specific crop and the type of irrigation system used to apply water to each crop vary.

Influence of water application losses on the total depth of water needed. Irrigation designer's account for the losses expected as water is taken from a source and delivered to the crop's root zone. This term is referred to as the Water Application Efficiency (WAE). For sprinkler irrigation systems, the WAE is usually assumed to be about 70% for a well designed and managed irrigation system. This means that when Table 3-8 indicates that a potato grower in Snyder County will be expected to apply 3.8 inches of irrigation water to the root zone during July of a 10-year drought year, this grower will take (3.8/0.7 =) 5.4 inches of water from his/her water source. Of this 5.4 inches taken from the water source, only 3.8 will be expected to reach the root zone. Therefore, for sprinkler irrigation all water-need depths must be increased by (1/.7 = 1.4), though this extra water will is not expected to be used (evapotranspired) by the crop. In reality some of this "lost" water is evaporated off the sprinkler spray and some is returned to the waters of the Commonwealth.

In Pennsylvania crops like corn and potatoes and some strawberries are usually sprinkler irrigated. Crops such as orchards, many vegetables, and some strawberries are drip or trickle irrigated. What difference does drip irrigation make on the water depths needed for irrigation? The water needed by the crop remains the same. However, the ability of a drip irrigation system to deliver this water to the crop's root zone is better than if sprinklers are used to deliver the water. Generally we assume a drip system has a WAE of about 90 to 95%. Thus the water that must be taken from the source in July (assuming these potatoes are drip irrigated) would be only (3.8/.95 =) 4.0 inches. This is one reason drip irrigation is considered superior to sprinkler when it is appropriate for it to be used.

**Influence of Crop Canopy.** When comparing sprinkler and drip irrigation, however, drip irrigation has another substantial "water-need" advantage. This second advantage is created because with drip irrigation, water is only applied to the plant; only the area under the plant's canopy is irrigated. An orchard makes an easy example. In an orchard with 12-foot diameter trees planted in rows spaced 20 feet apart, there will be an 8-foot wide path between the rows of trees. With drip irrigation only the trees (in this example only (12/20 =) 60% of the

total orchard area) are irrigated. The path is not. With sprinkler irrigation, the whole orchard area (trees and paths) would be irrigated.

Applying this concept to our examples means that when we sprinkler irrigate 3.8 inches of water on to an acre of potatoes in July, we must pump (3.8/.7 =) 5.4 in = 5.4 ac-in = 147,000 gallons of water to get 103,000 gallons (70%) to the crop's root zone. The grower drip irrigating an acre of orchard and wishing to apply 3.8 inches of water to his/her trees (use numbers from the example above), will only need to pump 65,000 gallons of water (3.8/.95 = 4.0 inches(.6) = 2.4 inches = 2.4 ac-in = 65,000 gal) and 62,000 gallons will reach the crop's root zone.

Crops that can effectively be drip irrigated, such as orchards, some vegetables and maybe strawberries all have different portions of canopy covers. We used 60% in the above example for orchards, but these percentages can vary greatly depending on how the trees or plants are planted and maintained. Likewise the canopy covers of one vegetable will be greatly different from another vegetable and the planting schemes will also greatly influence how much of the planted field will actually be irrigated. We often assume that if a crop's canopy cover is more than about 80% of the field area, drip irrigation is probably not a good idea. Sprinkler irrigation is better choice.

For purposes of this water assessment, only the acreage in orchards was assumed to be drip irrigated. Thus, the water needed volumes presented for orchards were adjusted downward by 60% assuming that all orchards will be drip irrigated. In reality the acreages were reduced by 60% to account for the effect of drip irrigation. Water volumes for all other crops were presented under the assumption that sprinkler irrigation would most probably be used to apply the irrigation water. The depths presented always represent the depth of water that should be needed by the growing plant. No adjustment has been made to account for losses.

#### **Consumptive Use Factors**

The Q<sub>7-10</sub> and annual volumes of water reported herein as needed by crop farmers for irrigation all assume that all of the water will be delivered to the plant root zone. Thus, it is fair to assume that the total volumes of the water reported will be consumptively used by the irrigated plants and returned to the atmosphere as either evaporated or transpired water.

This also assumes that when a farmer irrigates, he/she will be pumping more water than is reported in this report. If the farmer is using sprinkler irrigation, the volume pumped should be about 30% more than what the crop needs. Likewise, if the farmer is using drip irrigation, the volume pumped should be 5 to 10% more than what the crop needs.

### **Drought Conditions Influence Irrigation**

### **Rainfall Data**

Irrigation in Pennsylvania is dependent upon many factors. The most important of which is natural precipitation, or the lack thereof. In Pennsylvania, about 2 years in 10, there is sufficient natural precipitation to render irrigation unnecessary. Likewise, about 2 to 3 years in 10, there is such a large deficit in natural precipitation that without irrigation most crops yield very little quality produce. The remaining 5 to 6 years in 10, irrigation water is applied, as needed, to relieve occasional water stress. Thus it is important, in trying to estimate the irrigation water needed in Pennsylvania, that we include the influence of natural precipitation on the crop acreages that are expected to be irrigated in future years.

Precipitation data are available in many forms from many sources. The data we have found most useful were in the annual summaries of Climatological Data produced by U.S. Department of Commerce (USDC, 1978 to 2004). In these publications, Pennsylvania is divided into 10 sub-regions (see Figure 4-1), each containing 10 to 25 weather stations. The monthly precipitation data are summarized for each weather station in each sub-region for each month of each year. Then all the stations within each region were averaged on a monthly basis with its average deficit from normal.

The deviations from normal precipitation for each of the months between March and October were collected for each year between 1978 and 2004 for each of the 10 sub-regions.

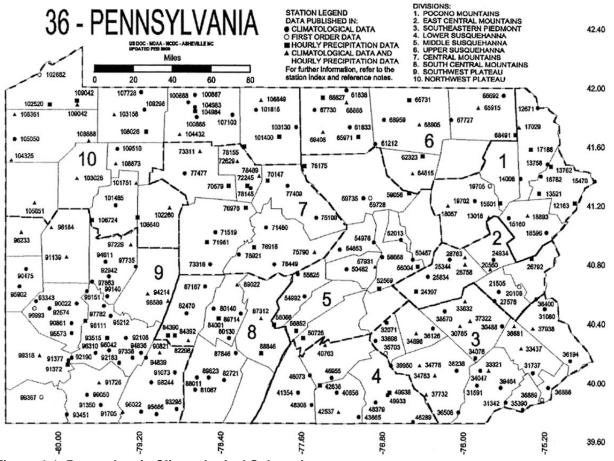

Figure 4-1. Pennsylvania Climatological Sub-regions.

By summing the regional monthly precipitation deviations over the March to October growing season, the growing seasonal precipitation deviations from normal were determined. These generated a 27-year annual series of seasonal precipitation deviations from normal that were then evaluated using a Log-Pearson Type III extreme probability analysis to yield the seasonal precipitation deficits expected on a drought return period basis. Thus the degree or level of drought was determined for each of the years when irrigated crop data were available.

Table 4-1 shows how the deviation from normal precipitation during the March to October growing season is related the drought return period for each of the 10 Pennsylvania sub-regions for the period from 1978 to 2004. From these return period data summaries it was possible to assign a drought return period to the rainfall deficit associated with each year the irrigated crop acreages were available from NASS. These drought return periods or rainfall deficits were then used with the historical NASS acreages for each crop to determine a crop-irrigated acreage expected in the years 2020, 2020 and 2030.

Return	Deviation from Normal during March to October Growing season (inches)									
Period				Pen	nsylvania	NSub-Reg	jion			
(Yrs)	1	2	3	4	5	6	7	8	9	10
1.01	7.50	8.50	10.00	12.00	8.30	6.70	6.90	8.50	7.10	8.00
2	1.39	0.86	0.68	0.14	1.02	1.26	0.73	0.19	0.39	1.53
5	-2.22	-2.36	-2.61	-3.44	-2.52	-2.16	-2.54	-3.00	-2.84	-2.39
10	-3.88	-3.87	-4.14	-5.01	-4.13	-3.76	-4.06	-4.48	-4.34	-4.14

100*	-7.08	-6.90	-7.13	-7.85	-7.23	-6.91	-7.07	-7.34	-7.25	-7.38

 Table 4-1. Deviation from Normal Precipitation for each Pennsylvania Sub-Region

 And Return Periods between 1.01 and 100 years.

\*The 100-year return period results are not reliable for n = 28 years of data.

It should be noted that when the irrigated acreages were extrapolated to 2010, 2020, and 2030, it was assumed that each of these years was under the influence of a 10-year return period drought. The appropriate return period, or rainfall deficit that occurred during each of the years for which the NASS data was available were also included and used in the linear regression analysis introduced in Chapter 2.

### **Current and Future Water Needed for Irrigation**

Based on the actual acreages downloaded from the 2002 NASS (2002) and the acreages predicted to be under irrigation in each County in 2010, 2020, and 2030, these acreages were multiplied times the growing season's irrigation water needed to yield the volumes of water needed reported herein. The  $Q_{7-10}$  (Kibler et al. (1977) and annual (PA-DER, 1978) irrigation water needed for each of the four years in question was adjusted to match the return period of the rainfall patterns for that year. Specifically, the drought return period experienced in 2002 in each of the 10 climatic regions ranged from a 1.2- to 1.8-year return period. In each county, the 1.01- and 2-year return period water needed for each crop in each county. The 10-year return period water need data from the PA-DER (1978) report was interpolated to yield the best estimate of the water that should have been needed for each crop in each county. The 10-year return period water need data were applied to the 2010, 2020, and 2030 projected acreages.

### Current and Future Q<sub>7-10</sub> Water Volumes Needed for Irrigation

The results of the current and future  $Q_{7-10}$  irrigation water needs assessment are presented in this chapter. It is strongly recommended that you read this chapter while near a computer where you can open and have available for reference the EXCEL Spreadsheets named "Irrigation Projection AnalysisA-C7" and "Irrigation Projection AnalysisD-Y7". The file named "Water Results7" also contains a summary of these irrigation results and will also be helpful. These files are on the CD at the end of this report.

Irrigated acreages were determined for each major crop along with the total acreage within each county by the procedures outlined in Chapters 2 to 4. The total acreages irrigated in each county in 2002 and those irrigated acreages projected for 2010, 2020, and 2030 are summarized in Table 5-1. These total irrigated acreages were summarized from the more detailed summary that includes the acreages of specific crops irrigated or expected to be irrigated in each of the counties in each evaluation year. These data are summarized in Appendix C. It is useful to observe from the results shown in Appendix C and summarized in Table 5-1, that the majority of the irrigated acreage in Pennsylvania occurred and will most probably continue to occur in a few select counties, see Table 5-2. The county with the largest irrigated acreage is Lancaster with just over 6,000 acres and expected to grow to upwards of 10,000 acres by 1030. These top ten irrigating counties currently (2002) account for 58% of the irrigated land in Pennsylvania and the top ten counties should continue to account for nearly 60% of the land irrigated in Pennsylvania. There is and will continue to be little or no irrigated land in several counties.

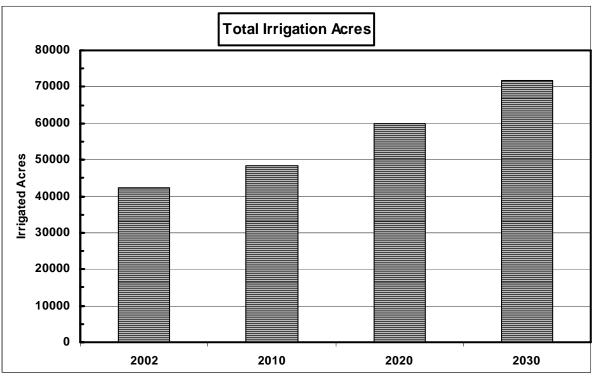

Figure 5-1. Total irrigated land in 2002, 2010, 2020, and 2030.

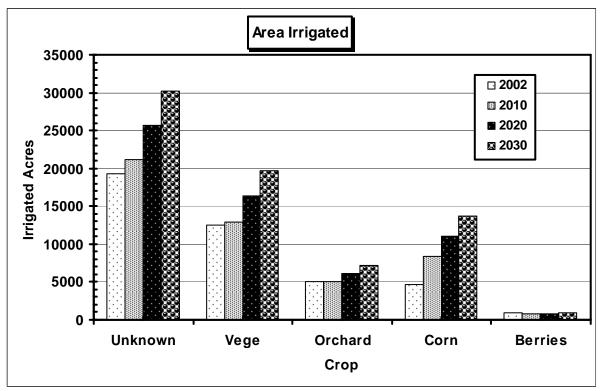

Figure 5-2. Irrigated area by crop in 2002, 2010, 2020, and 2030.

If we look at the overall irrigation picture, irrigated land is expected to continue to increase during the next few decades. Figure 5-1 shows the increase expected based on the four years evaluated in this study. There are currently (2002) 42,335 acres of land irrigated. By 2030, this is expected to increase to 71,640 acres, or

approximately (71640 - 42335 = 29305) 1,050 (29305/28) acres of new land is expected to be irrigated each year. Figure 5-2 shows how irrigated land area is expected to change with crop irrigated and year of interest.

#### Water needed for Irrigation

With the irrigated land areas established, these acreages (2002) and extrapolated acreages (2010, 2020, and 2030) were multiplied times the maximum monthly 7-day irrigation water needs (Kibler et al. (1977) developed for each crop in each county (see Chapter 3) and divided by seven to determine the maximum daily  $Q_{7-10}$  water needed for irrigation on a monthly basis. The maximum of the eight monthly  $Q_{7-10}$  water volumes were then selected and summarized to yield the maximum daily  $Q_{7-10}$  volume of water needed for irrigation in each county, see Table 5-3. The values shown at the bottom of each column are the maximum  $Q_{7-10}$  water needed for irrigation for the entire state of Pennsylvania assuming a 10-year drought occurred uniformly in all counties during the month with the greatest 10-year, 7-day water need.

These Q<sub>7-10</sub> irrigation water needed results and the detailed results from which these values were derived reveal many interesting concepts that may be helpful from the standpoint of the Pennsylvania "State Water Plan". By plotting the total water needed for irrigation against each of the years evaluated (see Figure 5-3), we can see the historical and precipitation evidence shows that use of water for irrigation is expected to grow over the next few decades. It should be remembered that part of the growth shown in Figure 5-3 is from the increased land area being irrigated (see Figure 5-1) and part is from the fact that the 2002 irrigation water need was based on the 1.2-to 1.8-year return period drought conditions that existed during the 2002 growing season. The future irrigation water needs, shown for 2010, 2020, and 2030, were based on a 10-year return period drought. However, even if the return period effect is removed, an irrigation water growth rate of approximately 2.0 to 2.5%/year must be planned for. Another factor that may actually increase this irrigation water use growth rate is that the Federal Government through the USDA-Natural Resources Conservation Service (NRCS) currently has two specific programs; one designed to encourage farmers to adopt irrigation as a crop management practice, and a second designed to help farmers already irrigating improve the efficiency of their irrigation systems.

In Table 5-2, the  $Q_{7-10}$  water needed for irrigation from Table 5-3 and the water needed for irrigation on a per acre basis were added to the two right-hand columns to show how irrigation water application changes from county to county within the top ten irrigating counties. If you examine the tables near the end of Appendix C, where similar information is presented for individual crops, these variations can be seen as well. The important issue is that the data from which the irrigated water quantities were derived (Kibler et al., 1977) assumed uniform drought conditions across the growing season—we used the 10-year drought for the 2010, 2020, and 2030 projections. Thus some  $Q_{7-10}$  irrigation water is recommended every month. In the typical, real world, every irrigator schedules his/her irrigation differently; some apply water independently of natural rainfall, some apply water only when the crop(s) show signs of severe water stress, others only irrigate during those periods when the crops are in what is referred to as the "Critical Period" of crop growth. The Critical Period varies from crop to crop. The crops for which we had NASS data will need irrigation most critically during the months shown in Table 5-4.

Table 5-4. Critical Periods for crops evaluated in this study (USDA-SCS, 1972).

Crop	Critical Period	Critical Months
Corn	Tasseling, silking	Late July, Early August
Vegetables	Varies with crop	April to August
Orchards	Fruit enlargement	July, August
Berries	Fruit enlargement	May to early June
Potatoes	Blossom to harvest	June to September

The water use results shown for crops like corn, orchards, and berries are most likely quite reliable. The results shown for the "Vegetables" category and especially the "Unknown" category reflect the water needs of a wide variety of crops. For example it is my best guess that much of the 'unknown" irrigated crop in Erie County is applied to grapes, while the unknown crop(s) in counties like Berks or Schuylkill Counties is most likely potatoes. My contacts at NRCS tell me many irrigation adopters are looking to irrigate sweet corn. Note: Prior to 2002, NASS included "sweet corn" and "potatoes" as "irrigated acreage" categories in their data base. These breakout categories were dropped in the 2002 census.

Another useful piece of information from Table 5-2 is how the volume of water needed for irrigation varies with the drought return period. For 2002, when Pennsylvania had a very mild drought (T = 1.2- to 1.8-year return period) approximately 0.0033 MGD of irrigation water was needed on a  $Q_{7-10}$  basis for each acre of land irrigated. During the 10-year drought used for the 2010, 2020, and 2030 extrapolation, each acre of irrigated land will need approximately 0.0050 MGD of irrigation water during the  $Q_{7-10}$  event.

Figure 5-4 shows how the volume of water needed for irrigation varies with crop and year if interest.

Before we close this chapter on how much water Pennsylvania agriculture has used and will most likely need on a  $Q_{7-10}$  basis for irrigation during the next few decades, it is worth including a few comments about the reliability of these results and the estimates for the future. A great deal of science was brought to bear on the 1982, 1987, 1992, 1997, and 2002 NASS data to establish the present and future irrigation water needs. It must be remembered that the results are no better than the raw data. We have taken the NASS data at face value. I know from experience and from interacting with farmers, that there are few if any farmers who consider their report to NASS as important or "any of the government's business". Many farmers refuse to fill out the questionnaire and many provide "loose" estimates. The farming community generally considers the "government" an entity they dislike and many refuse to cooperate with it in any way. They mostly fear that data reported will

eventually return to them in some way that will restrict their freedom or cost them money in the form of taxes, levies, or lower prices for their produce. Thus even the 2002 (present conditions) results reported must be considered to have a large error. If someone were to ask me how many acres of Pennsylvania were irrigated in 2002, I would respond with "about 40,000 acres, maybe a few more".

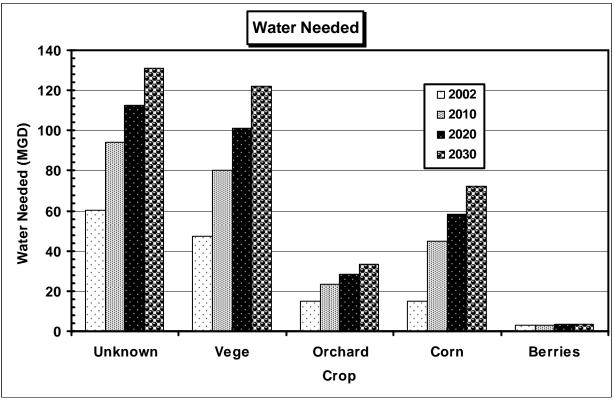

Figure 5-4. .  $Q_{7-10}$  irrigation water needed by crop in 2002, 2010, 2020, and 2030.

This then raises questions about how good the projected irrigated land acreages are for 2010, 2020, and 2030. As described earlier, these projections were based on a multiple linear regression using "Year of interest" and "Growing season rainfall deficit from normal" as independent variables. This regression approach was applied to the historical acreages of "corn", "vegetables", "orchards", "berries", and the "total acres irrigated" in each county. The "unknown" projections were determined by differences. It should be remembered that during the past 20 years, there were only five sets of data available. Obviously I feel better about the predicted results in 2010 than in the later years. With "big" agricultural operations being planned and implemented, major shifts in crop acreages and irrigation practice can occur in just a few years.

I guess the bottom-line is that I do not believe the numbers in this report to be better than one or 1.5 significant figures. It is my hope that the reader will not get too hung-up in minor differences.

### **Current and Future Annual Water Volumes Needed for Irrigation**

The results of the current and future irrigation annual water needs assessment are presented in this chapter. It is strongly recommended that you read this chapter while near a computer where you can open and have available for reference the EXCEL Spreadsheets named "Irrigation Projection AnalysisA-C" and "Irrigation Projection AnalysisD-Y". The file named "Water Results" also contains a summary of these irrigation results and will also be helpful. These files are on the CD at the end of this report.

Irrigated acreages were determined for each major crop along with the total acreage within each county by the procedures outlined in Chapters 2 to 4. The total acreages irrigated in each county in 2002 and those irrigated acreages projected for 2010, 2020, and 2030 were summarized in the first part of Chapter 5 and Appendix C.

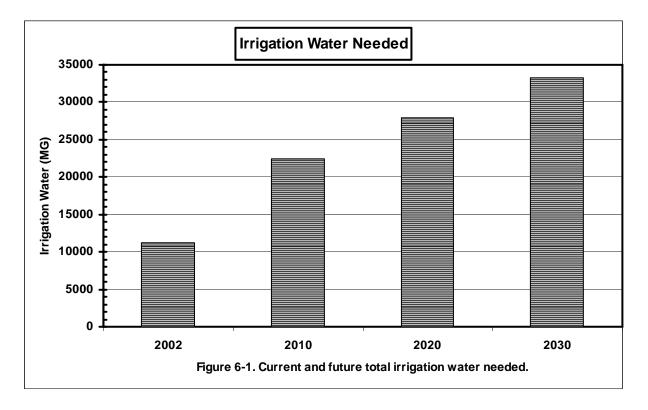

#### Annual Water needed for Irrigation

With the irrigated land areas established, these acreages (2002) and extrapolated acreages (2010, 2020, and 2030) were multiplied times the monthly irrigation water needs (Kibler et al. (1977) developed for each crop in each county to determine the monthly water needed for irrigation. These monthly water volumes were summed to yield the annual volume of water needed for irrigation in each county in million gallons (MG), see Table 6-1. The totals shown at the bottom of each column are the total water needed for irrigation for the entire state of Pennsylvania.

Total =	11265	22463	27863	33276

As with the maximum daily water needs reported in Chapter 5, the trends shown here are similar. Water needed on an annual basis to support irrigation in Pennsylvania is expected to grow at a rate of 2 to 2.5%/year. Likewise the assessment of the top ten counties in land irrigated and annual irrigation water used are also similar, see Table 6-2. If you examine the tables near the end of Appendix E, the trends are similar for the individual crops.

Another useful piece of information from Table 6-2 is how the volume of water needed for irrigation varies with the drought return period. For 2002, when Pennsylvania had a very mild drought (T = 1.2- to 1.8-year return period) approximately 0.27 MG of irrigation water was needed annually for each acre of land irrigated. During the 10-year drought used for the 2010, 2020, and 2030 extrapolation, each acre of irrigate land will need approximately 0.47 MG of irrigation water annually.

PART II

**Animal Water Needs Assessment** 

### **Extrapolating Animal Populations**

The animal water needs assessment consisted of three parts; (1) estimate the present animal water needs for each county based on the most recent animal populations available, (2) extrapolate the historical animal populations to predict the 2010, 2020, and 2030 irrigation water needs in each county, and (3) attempt to estimate what portion of the animal producers in each county have already registered (or have not registered) their water use with PADEP. The present (part 1) and extrapolated (part 2) animal water needs assessment for each county and the state are contained in two attached EXCEL spreadsheets named "Animal Projection Analysis\*.xls", where the "\*" refers to the first letter of the counties contained in the spreadsheet. For example "Animal Projection AnalysisM-Y" contains the data and analysis for the counties whose names begin with the letters "A" to "M". The remaining counties are in the second spreadsheet. Both spreadsheets are laid out the same. Both spreadsheets also have a "7" to reference the analysis in units of million gallons per day (MGD). Both spreadsheets contain worksheets named "BaseA", and "Animal", which contain the data and various analyses performed. Both spreadsheets also contain a "Summary" worksheet that summarizes the county-by-county results. The county and state animal and irrigation water need results are also combined and presented in a separate spreadsheet named "Water Results7", also found on the Report CD.

The registration analysis (part 3) for each County and the state is contained in the attached EXCEL spreadsheet named "Registration Analysis". The sheets named "BaseA", and "Animal" contain the data and the various analyses performed.

#### **Animal Populations Available**

NASS collects and reports a wide variety of animal populations in each County. These are divided into several large categories including Cattle (Bovines), Swine, Sheep, Goats, Horses, and Poultry. In some of these categories, populations are collected in several sub-categories such as the Cattle populations include "Cattle and Calves", "Cows and Heifers that calved", "Beef Cows", "Milk Cows", and Steers and Bulls". The poultry category includes "Chickens 3 mon +", "Hens and pullets", "Broilers and Meat Birds", and "Turkeys". Because of the water use data available from NASS and the need to assign water use data to each group of animals, some of the animal populations taken from the NASS statistics were adjusted and combined as described below.

As with the acreages of irrigated land in each county, one of the difficulties with trying to use NASS data is that NASS is careful to protect the reporting farmers from identification. Therefore, when a county has only a one, or a few, farmers reporting animals in a category, they reported how many farmers reported animals in that group, but they did not identify how many animals were reported. For instance, under hogs in Cameron County in 1987, there were only 3 farmers reporting. Therefore, NASS reports the "3" hog farmers, but because it might be possible for a local person to figure out which specific farmers these three farmers might be, NASS did not report the number of hogs these three farmers owned; instead they simply report the acreage as "(D)". These holes in the data sets caused some concern during this analysis because on the one hand it is misleading to report the "(D)" as zero hogs, but it is also impossible to know how many hogs were grown. This problem was solved by artificially inserting a number into the analysis. These numbers varied with the different animals. In the case of large animals (cows, horses, etc), I assumed a "(D)" was equal to 5 animals. In the case of smaller animals (hogs, chickens, etc) the "(D)" was assumed to be 10 animals. In a few cases, larger estimates were used. If you look at the specific data in the spread sheets, these estimated values are evident because they are rounded to 1 or 2 significant figures while the actual NASS data are reported to the last animal.

**Cattle.** The water use data available for cattle was limited to "Milk Cows", "Other Adult Cows", and "Young Cows". Therefore the animal populations taken from NASS were adjusted as follows. It should be noted that between 1997 and 2002, NASS changed the way they combined "Steers and Bulls" and "Heifers", thus the adjustment is different for the different years:

- Milk Cows = Milk Cows (no adjustments were made)
- Young Cows (1982, 1987, 1992, and 1997) = Cattle & Calves Beef Cows Milk Cows Steers & Bulls. Because of the change in reporting in 2002, the category "Young Cows = Cattle & Calves - Beef Cows – Milk Cows - (1/3)Other Cattle. The 1/3 was an approximation of how many of the Other Cattle were thought to be young stock.

- Other Adult Cows (1982, 1987, 1992, and 1997) = Cattle & Calves Milk Cows Young Cows (defined above). In the 2002 NASS data, the old category of Steers and Bulls was changed to "Other Cattle", which changed the category "Other Adult Cows" = Cattle & Calves Milk Cows Young Cows (defined above).
- Young Cows (1982, 1987, 1992, and 1997) = Cattle & Calves Beef Cows Milk Cows Steers & Bulls. Because of the change in reporting in 2002, the category "Young Cows = Beef Cows + (1/3)Other Cattle.

**Other Animal Populations.** The other animal populations were used and reported directly as presented in the NASS statistics.

#### **Present Animal Water Volume**

The present animal water needs in each County were estimated from the animal populations reported in NASS (2002). These animal populations were multiplied times the daily water volume needed by each individual animal type (see Chapter 8) to determine the volume of water needed for animals in each County under the present circumstances. These data and analyses are in the two EXCEL spreadsheets named "Animal Projection Analysis\*.xls".

#### **Extrapolated Future Irrigated Water Volume**

The extrapolated animal water prediction for 2010, 2020, and 2030 was based on a linear equation fit to the historical animal populations from 1982, 1987, 1992, and 1997 (NASS, 1982, 1987, 1992, 1997) and the animal populations for 2002 used to determine the present water needs.

The procedure for extrapolating the historical animal populations between 1982 and 2002 to predict the animal populations expected in the future years of 2010, 2020, and 2030 was based entirely on drawing a straight line through the historical animal populations attempting to take into account how these populations had changed during the past 20 years. This extrapolation procedure was applied to each of the three cattle categories, the four poultry categories, and the swine, sheep, goats, and horse categories in each county. The results of each extrapolation are shown with the animal data and plotted in one of the three graphs located to the right of each county's animal data in the attached "Animal Prediction Analysis" spreadsheets.

#### **Assessment of Present Registrations**

Included in NASS (2002) are data that tell how many farms with various animal populations are located in each county. The farm-size data available includes "Cattle and Calves", "Beef Cows", "Milk Cows", "Steers and Bulls (Other Cattle)", "Hogs and Pigs", and "Layers". By knowing how much water is likely to be needed by each type of animal, we could determine approximately how many of each type of animal would need to be grown (or kept) on each individual farm before that farmer's animals probably used more than the 10,000 gpd trigger volume required for registration. PADEP also supplied the results of the individual farmer water registrations. By making several reasonable assumptions we were able to determine an estimate of each of the following parameters for each county:

- Total number of farms with each type of animal.
- Number of farms with a large enough numbers of animals to require registration based on the 10,000 gpd registration limitation.
- Number of animal production farms that already registered.
- Total water needed for animal production in MG.
- Total animal production water registered in MG.

These results are located in the "Animal" sheet of the attached "Registration Analysis" spreadsheet and summarized in Part IV.

### **Animal Water Needed**

The production of animals and associated meat and milk require considerable quantities of water. Before we attempt to suggest levels of animal water use for each type of animal raised in Pennsylvania, let's take a look at a rather detailed analysis of animal water use to demonstrate the complexities of determining appropriate animal water use values. Thus we have developed three relevant examples. These examples include determination of water use, respiration, and waste production for three specific animals; a 1400-pound dairy cow, a 125-pound pig, and a 4-pound laying hen. The data used in these examples were obtained from Esmay and Dixon (1986) and Midwest Plan Service (1985).

#### 1400-Pound Dairy Cow; Typical Holstein

A typical 1400-pound dairy cow, milking 80 pounds of milk per day, takes in about 23 gallons of water each day. Of these 23 gallons, eight gallons are converted into milk. Of the remaining 15 gallons of water (23 - 8 = 15), 12 gallons appears in the cow's waste (fecal plus urine). The water in the waste stream will be returned to the hydrologic cycle as a liquid or vapor depending on how the farmer manages his/her waste operation. The other 3 gallons is respired to the atmosphere. Finally, each dairy operation uses additional water to clean the milking equipment and flush manure from within the production facility. Midwest Plan Service (1985) encourages dairy operations to add an additional 7 gallons per day for each animal's water need to cover these clean-up uses. Therefore, a dairy cow uses, on average about 35 gallons of water per day; 23 gallons are consumed and 12 more is used to make the milking operation function.

If we assume the milk (8 gpd) is consumed within Pennsylvania and converted to waste via digestion that is returned to Pennsylvania, the cow's waste (12 gpd) is returned to the waters of Pennsylvania, and the cleanup water (12 gpd) is also returned to the waters of Pennsylvania, then only the 3 gpd of respired water is consumed. Thus the consumptive use for a daily cow is only (3/35) 9%. If one assumes the milk is shipped outside of Pennsylvania, then the consumptive use increases to (11/35) 31%.

Non-milking adult cows will drink about 15 gpd and respire about 3 gpd, yielding a consumptive use of only (3/15) 20%. This is a reasonable value for young cattle as well.

On the other hand some will argue that water consumed and returned in the animal's waste stream is also consumptively used. If this is true (which I disagree with) the a milk cow consumptively uses (12/35) 34% and non-milk cow consumptively use 100%.

### 125-Pound Pig

Each 125-pound pig will usually use about four gallons of water per day. Of this four gal/pig/day, about 0.75 gal/pig/day is respired and 1.07 gal/pig/day is discharged in the waste (fecal and urine). The remainder of the water is wasted (pigs are sloppy drinkers).

### 4-Pound Laying Hen

Four-pound laying hens take in about 0.08 gallons of water each day. About half or 0.04 gal/hen/day is respired.

### Animal Design and Consumptive Use Rates

Based on evaluations similar to those discussed above, we have developed estimates for each of the animal categories in the NASS data by using the water use data available (Esmay and Dixon, 1986; and Midwest Plan Service, 1985). The design water needs of each animal category are summarized in Table 8-1. The design values shown in Table 8-1 tend to be those used by agricultural planners based on the larger animal in each category. Thus, there was a tendency to over estimate the water used by animals in some of the groups. The daily water use values in Table 8-1 were used in this analysis. The last column of Table 8-1 contains an estimate of the percentage of he design volume that should be considered consumptive use or

Animal Groups	Design Animal Use (Gallons/Animal/Day)	Consumptive Use Factors (%)
Milk Cows	35	9 to 31
Other Adult Cows	15	20
Young Stock	11	20
Hogs & Pigs	4	20
Sheep & Lambs	2	20
Goats	2	20
Horses & Ponies	12	20
Chickens (3 months +)	0.055	50
Hens & Pullets	0.06	50
Broilers & Meat Birds	0.08	50
Turkeys	1.2	50

 Table 8-1. Daily Design and Consumptive Water Use by Farm Animals.

### **Current and Future Water Needed by Animals**

The results of the current and future animal water needs assessment are presented in this chapter. It is strongly recommended that you read this chapter while near a computer where you can open and have available for reference the EXCEL Spreadsheets named "Animal Projections Analysis\*.xls" and "Animal Projections Analysis\*.xls". The "\*" in the two previous file names refer to the first letter of the county names in each file. There is also a "7" in the file name to denote the water use units of MGD used to present the results. The file named "Water Results7.xls" also contains a summary of these animal use results. These files are on the CD at the end of this report.

Animal populations were determined from the NASS statistics for evaluation years 1982, 1987, 1992, 1997, and 2002 for each major species within each county and extrapolated to predict animal populations expected in 2010, 2020, and 2030 by the procedures outlined in Chapters 7 and 8. The current (2002) animal populations in each county and those predicted for 2010, 2020, and 2030 are summarized in Appendix F. These tables and related animal population data can be found in the "Water Results7" spreadsheet.

Animal populations are projected to change over the next few decades. Figures 9-1 to 9-6 show the current and projected animal populations for the major species raised in the State of Pennsylvania. These six figures are shown in descending order of the volume of water each species will need starting with cattle, which need the largest volume of water and ending in Figure 9-6 with goats, which needs the smallest volume of water. These six figures give a visual picture of what each species' population is (or was) in 2002 and how, based on the county-by-county and species-by-species extrapolations performed, during this analysis, and how the population of each species is expected to change during the next 28 years. From Figure 9-1 we can easily see that cattle populations are expected to decline. The milk cow populations are expected to decline about 9,000 head over the next 28 years or about 300 head/year. The decline in adult cows (most of these are beef cattle) and the decline in young stock is slightly less, but an overall decline in cattle population is predicted. All of the other species, for which we had data, showed growth trends over the next 28 years. These growth rates varied from about 2%/year for several poultry groups to as high as 3.5%/year for goats. In summary, except for slowly declining cattle populations, other animal populations are expected to increase over the next three decades. Current and projected animal populations are shown for each county in Section 1 of Appendix F.

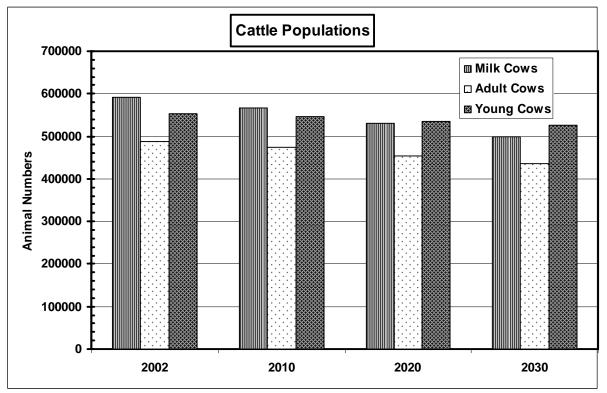

Figure 9-1. Current and predicted cattle populations.

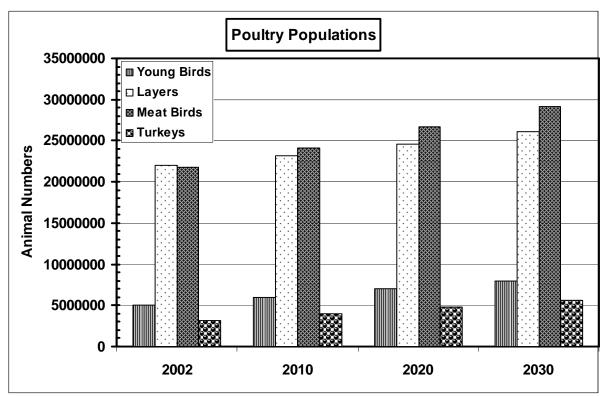

Figure 9-2. Current and predicted poultry populations.

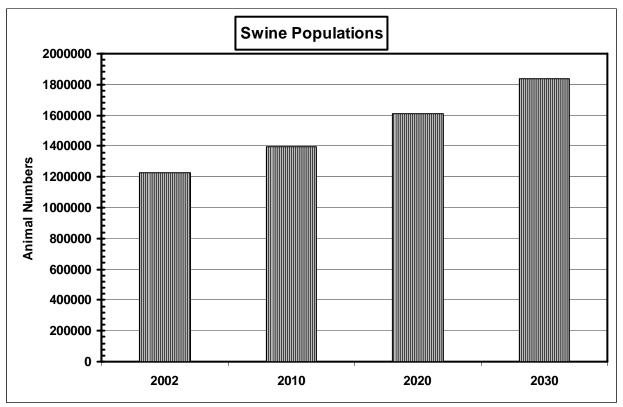

Figure 9-3. Current and projected swine populations.

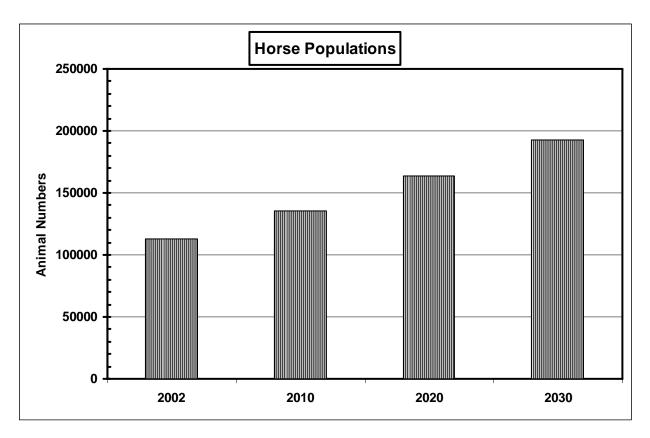

Figure 9-4. Current and predicted horse populations.

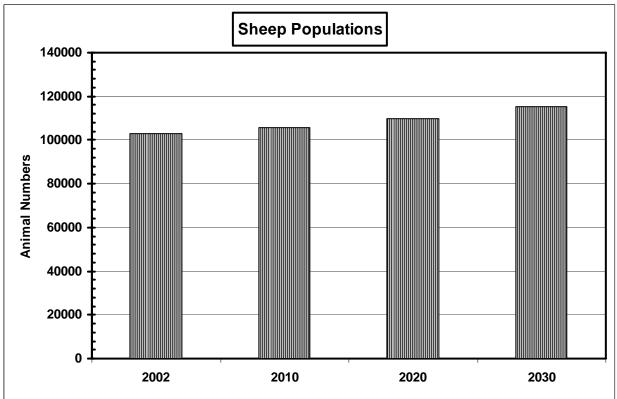

Figure 9-5. Current and predicted sheep populations.

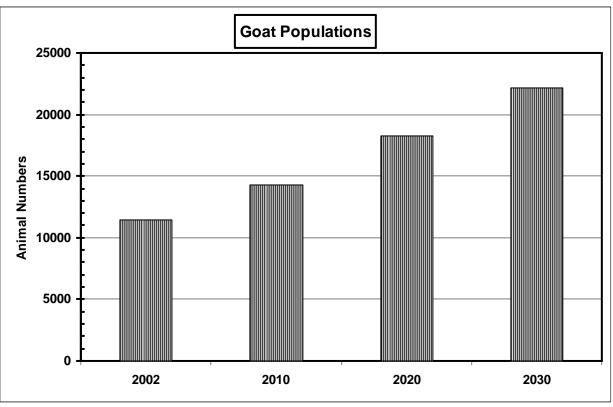

Figure 9-6. Current and predicted goat populations.

### Animal Water Needed

By multiplying the animal populations times the daily water use volumes needed by each species presented earlier, the volume of water needed to sustain these animal populations was determined. The detailed water volumes needed to raise each species in each county are presented in Section 2 of Appendix F. The total water needed for all animals in each county is shown in Table 9-1 for the current conditions (2002) and for 2010, 2020, and 2030 extrapolations.

As with the irrigation analysis, it is useful to observe from the results shown in Section 2 of Appendix F, that the majority of the water needed to raise animals in Pennsylvania is (and will) be needed in a few select counties, see Table 9-2. The county with the largest animal water need is Lancaster where approximately 9 MGD of water is or will be needed for animals. These top ten animal-producing counties currently (2002) account for 53% of the animal water needed in Pennsylvania and the top ten counties should continue to account for nearly 60% of the animal water needed in Pennsylvania.

These animal water needed results and the detailed results from which these values were derived reveal many interesting concepts that may be helpful from the standpoint of the Pennsylvania "State Water Plan". By

plotting the total water needed for animals against each of the years evaluated (see Figure 9-7), we can see that the historical evidence shows that animal water needs are expected to grow over the next few decades. The rate of growth in animal water needed resulting from this study was an annual growth rate of about 0.2%/year (90,000 gal/day/year).

Before we close this chapter on how much water Pennsylvania agriculture has used and will most likely need for animal production during the next few decades, it is worth including a few comments about the reliability of these results and the estimates for the future. A great deal of science was brought to bear on the 1982, 1987, 1992, 1997, and 2002 NASS data to establish the present and future animal water needs. It must be remembered that the results are no better than the raw data. We have taken the NASS data at face value. I know from experience and from interacting with farmers, that there few if any farmers who consider their report to NASS as "important" or "any of the government's business". Many farmers refuse to fill out the questionnaire and many provide only loose estimates. The farming community generally considers the "government" an entity they dislike and most refuse to cooperate with it in any way. They mostly fear that data reported will eventually return to them in some way that will restrict their freedom or cost them money in the form of taxes, levies, or reduced prices for their produce. Thus even the 2002 (present conditions) results reported must be considered to have a large error. If someone were to ask me how much water is needed for animals in Pennsylvania in 2002, I would respond with "about 50 MGD, maybe a bit more".

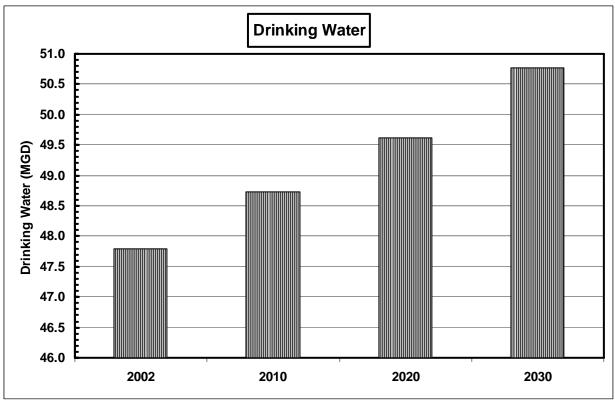

Figure 9-7. Current and predicted animal water needed.

This then raises questions about how good the projected animal water needs are for 2010, 2020, and 2030. As described earlier, these projections were based on my best-guess at a straight-line extrapolation using the NASS acreages from the past 20 years. It should be remembered that during the past 20 years, there were only five sets of data available. Obviously I feel better about the predicted results in 2010 than in the later years. With "big" agricultural operations being planned and implemented, major shifts in animal production units can occur in just a few years.

I guess the bottom-line is that I do not believe the numbers in this report to be better than one or 1.5 significant figures. It is my hope that the reader will not get too hung-up in minor differences.

PART III Summary of Irrigation and Animal Water Needs

### **CHAPTER 10** Current and Future Maximum Daily Water Needed by Irrigation and Animals

The analysis used to determine the water needed for irrigation was presented in Part I. The maximum daily irrigation water needs ( $Q_{7-10}$ ) were presented in Chapter 5 with supporting data summarized in Appendices C and D. The supporting data and computations are in files named "Irrigation Projection AnalysisA-C7.xls" and "Irrigation Projection AnalysisD-Y7.xls" and summarized in a file named "Water Results7" all of which can be found on the CD at the end of this report.

The analysis used to determine the daily water needed for animals was presented in Part II. The results of this assessment were presented in Chapter 9 with supporting data summarized in Appendix F. The supporting data and computations are in files named "Animal Projection AnalysisA-M7" and "Animal Projection AnalysisM-Y7" and summarized in a file named "Water Results7" all of which can be found on the CD at the end of this report.

The purpose of this chapter is to present the combined daily irrigation ( $Q_{7-10}$ ) and daily animal water needed currently (in 2002) and projected to be needed by agriculture in 2010, 2020, and 2030. The numerical summary for each of the four evaluation years are shown in Tables 10-1 to 10-4. The final agricultural water-use totals are shown in Figure 10-1. It is evident from the data summarized here that agricultural water use is expected to grow over the next 28 years. Water needed for raising animals will grow slightly, from 48 to 51 MGD. The 10-year, 7-day maximum ( $Q_{7-10}$ ) water needed to support irrigation of agricultural crops is expected to grow more rapidly, from 140 to 360 MGD. The water needed for animals will be nearly uniformly distributed across the year while the water needed for irrigation will be needed only during periods that match the  $Q_{7-10}$  criteria.

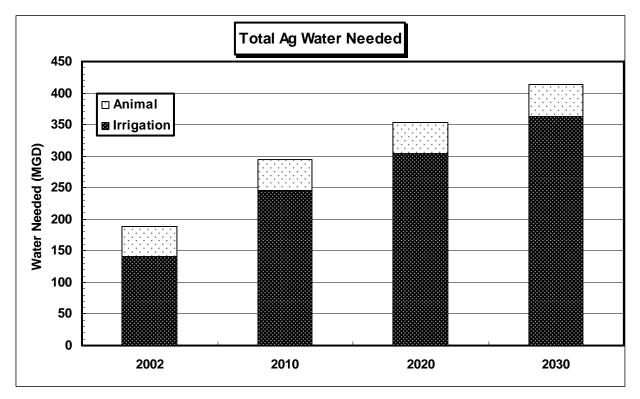

Figure 10-1. Total maximum daily agricultural water currently (2002) needed and expected to be needed in 2010, 2020, and 2030.

As noted in Chapter 9, there is an important rainfall-driven factor that greatly influences the volume of irrigation water needed in any given year. The projections of the volume of irrigation water needed in 2010, 2020, and 2030 was based on a 10-year return period drought occurring during each of these three evaluation years. If growing-seasonal rainfall is nearly normal (or above normal), daily water needed for irrigation will be less than those values shown. If, on the other hand, growing-seasonal rainfall is less than expected during a 10-year drought, water needed for irrigation could be greater than those values shown above.

### Monthly Distribution of Maximum Agricultural Water Needed

It maybe useful to see how the daily maximum agricultural water use is expected to be distributed among the 12 months of the calendar year. If you remember, maximum daily irrigation water needed to supplement rainfall was presented based on the results of a study by Kibler et al. (1977), who showed that, based on the drought return period, different amounts of irrigation water will be needed in different months during the growing season from March through October. Irrigation water would not normally be needed during the dormant winter months. On the other hand, animals are typically raised in the context of an annual population that does not normally change much throughout the year. Thus for animals, water is needed at approximately the same volume every month of the year. The maximum daily water volumes presented above were parceled into monthly volumes for irrigation and animal use for each of the four evaluation years. The numerical data are shown in Tables 10-5 to 10-8 and plotted in Figures 10-2 to 10-5. The results shown in Tables 10-5 to 10-8 and plotted in Figures 10-2 to 10-5 assume a Q<sub>7-10</sub> drought in each month that causes the maximum daily irrigation to occur in each month. It was not considered appropriate to sum the monthly values so no total annual value is given.

Monthly Water Needed		Animals	Irrig.	Total

Table 10-8. Monthly distribution of agricultural water needed in 2030.

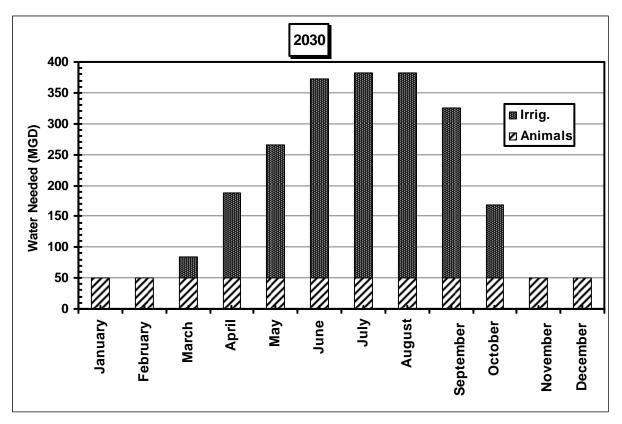

Figure 10-5. Monthly distribution of agricultural water needed in 2030.

The overall summary of how much water Pennsylvania agriculture used in 2002 is about 188 MGD. In the future maximum daily agricultural water used is expected to increase in 2010 to about 294 MGD based on the occurrence of a 10-year drought in 2010, increase in 2020 to about 354 MGD based on the occurrence of a 10-year drought in 2030 to about 414 MGD based on the occurrence of a 10-year drought in 2030. In this context it is assumed that the 10-year drought will occur uniformly across Pennsylvania and that the  $Q_{7-10}$  daily maximum water volumes will be needed every where at once.

# PART IV

**Registration Analysis** 

### Water Registration Assessment Procedure

After annual water volumes needed by agriculture to irrigate crops and grow animals were determined for the current conditions (2002) and extrapolated to 2010, 2020, and 2030, (see Chapters 6 and 9) these results were compared on a county-by-county basis to the water registration results provided by PADEP. In addition to the acreage irrigated and animal populations, which were instrumental in helping to determine the volume of water needed by the farmers in each county, the NASS data also provided additional information about "Irrigated Acreage by Farm Size" for each county. These data were presented in a form similar to that shown in Table 11-1. The "farm size" categories, "number of farms", and "acres irrigated" were taken directly from the 2002 NASS data. The last column labeled "acres irrigated per farm" was added to summarize the average farm size represented by each category. In cases where "acres irrigated" were not given (the blanks) because of confidentiality issues, the average irrigated area per farm was not available. From these data, and the knowledge that only 2 to 3 acres of cropland needed to be irrigated before a farmer was most likely applying more than 10,000 gpd of irrigation water, we were able to estimate how many irrigating farms were large enough to require registration. In Adams County, for example, farms in all size categories except the "1 to 9 acres" category are most likely irrigating enough water to require registration with PADEP. In other words 91 of the 114 irrigating farmers in Adams County should most probably have registered their water use.

Farms w/Irrigation =		114	
Acres Irrigated =		2656	
Irrigated Acres By Fa	rm Size		Acres Irrig.
Acres	# Farms	Acres Irrig.	per Farm
1 to 9	23	47	2.0
10 to 49	33	97	2.9
50 to 69	2		NA
70 to 99	10	66	6.6
100 to 139	11	222	20.2
140 to 179	3		NA
180 to 219	5	82	16.4
220 to 259	4		NA
260 to 499	8	259	32.4
500 to 999	9	1139	126.6
1000 to 1999	4	330	82.5
>2000	2		NA

Table 11-1. NASS data on "Irrigated Acres By Farm Size" for Adams County in 2002.

Based on the registration data supplied by PADEP, we were able to estimate that 11 irrigating farmers had already registered their water use totaling 31 MG/year. This 31 MG/yr was compared to the 569 MG/yr all irrigators in Adams County should most likely have been applying.

### PADEP Water Use Registration Data

PADEP provided a summary of the agricultural water use registration data. These data included "County", "Location", "Annual Withdrawal", "Annual Days this water was Used", and a monthly breakdown of "volume used" and "days used" each month. First the registration data were sorted by county. These sorted registration data are in the "Reg" sheet of the "Registration Analysis" spreadsheet (see the CD at the end of this report). Then in order to identify whether a farmer was using the water for irrigation or animal agriculture, we used the given monthly data as follows:

- If the water was withdrawn nearly uniformly over all months, the farmer was assumed to be supplying the water to animals. No data was provided about what animals might be being raised.
- If the water was withdrawn only during selected growing season months, the farmers were most likely irrigating crops. No data was provided about what crops might be irrigated.

- When the registered annual volume of water was given as "0", we could not use the data (marked in yellow). We have no idea what these represent.
- If the registered annual volume of water included no monthly breakdown, it was impossible to determine whether the water was to be used for animal or crop irrigation purposes. These too are marked in yellow.

The average water volume registrations for the months of January, February, November, and December were used to estimate the animal use. Any registered water over and above this "animal" average was considered to be irrigation water.

#### **NASS Animal Data**

The NASS data base also included a detailed breakdown of how many farms contained "how many animals". These details were given for several animals sub-groups. These data were used to estimate how many farms should have been registering animal water use in each county. The animal data available relating to farm size and animal populations in each county included:

- Farms with cattle,
- Farms with Beef cows,
- Farms with Milk cows,
- Farms with Other Cattle,
- Farms with Hogs, and
- Farms with Layers.

### Table 11-2. NASS data on "Farm w/ Milk Cows" for Adams County in 2002.

		10000 gpd	
		Flag =	286
	Farms w/Milk Cows =		60
	Total Milk Cows =		7280
Farm Size			Milk Cows
# Animals	# Farms	# Milk Cows	per Farm
1 to 9	5	6	1
10 to 19	4	66	17
20 to 49	16	540	34
50 to 99	21	1454	69
100 to 199	6	907	151
200 to 499	5	1127	225
> 500	3	3180	1060

These data were developed and used similar to those described earlier for irrigation. Table 11-2 shows the "Farms with Milk Cows" for Adams County in 2002. The first three columns were taken directly from the NASS data. The last column we added to determine the average number of milk cows on a typical farm in each category.

Note that the number at the top of the table tells how many milk cows can be raised on a farm before the farmer should be using more than 10,000 gpd of water. Again, the farms large enough to have more than the 286 head/farm were those identified as needing registration. In Adams County only 3 farms were (on average) large enough to require registration.

Each animal group for which these data were available was similarly evaluated and added to the 3 farms with milk cows to determine the number of animal farms that should probably be registering from Adams County. After looking at all of the animal groups, we identified 21 farms that should have been registered to use more than 10,000 gpd for animal production in Adams County. A complicating factor was that this analysis assumed no farmer was raising more than one species of animal. If a farmer was raising enough hogs to require registration and also raising enough milk cows to require registration, this farmer would most likely be counted twice as a potential registrant.

The results of this analysis are given in Chapter 12.

### Water Registration Assessment Results

The PADEP Water Registration data were evaluated to determine how many farmers had registered and what volume of water was registered in each county. When monthly data was available, it was possible to split out the number of registrants and volume registered pertaining to raising animals and irrigating crops. These data were evaluated and are summarized in Tables 12-1 for irrigation and Table 12-2 for animals.

In Table 12-1, for each county, the annual "irrigation water needed", "the number of farms that should be registering irrigation water", "the volume of irrigation water that was actually registered", and the number of farms that registered irrigation water" are shown. In most counties the volume of water registered is less (in many counties, much less) than the volume of water our analysis shows may be needed for irrigation in that county. There are a few counties where the volume of water registered was greater than the volume of water our analysis suggests will be needed. (More about this later). The totals for the state are shown at the bottom of Table 11-1. Here, for the whole state we see that, based on the data available, 8,700 ac-ft of the 33,000 ac-ft needed for irrigated agriculture was registered. This registered water was from 199 of the 3039 farms that should probably be registering irrigation water use.

In Table 12-2, for each county, the "animal water needed", "the number of farms that should be registering animal water", "the volume of animal water that was actually registered", and the number of farms that registered animal water" are shown. As with the irrigation analysis, in most counties the volume of water registered is less (in many counties, much less) than the volume of water our analysis shows may be needed for animals in that county. There are a few counties where the volume of water registered was greater than the volume of water our analysis suggests will be needed. (More about this later). The totals for the state are shown at the bottom of Table 12-2. Here, for the whole state we see that, based on the data available, 11,900 MG of the 17,500 MG needed for animal agriculture was registered. This registered water was from 482 of the 721 farms that should probably be registering animal water use.

#### **Registration Summary**

The registration analysis, to this point was not able to show the total volume of agricultural water that was registered because many of the registrations did not provide a monthly breakdown of when the water would be used. In addition, it became evident that there was poor correlation between the volume of water needed, for both irrigation and animals, and the volume of water actually registered. In an attempt to show more clearly the total registration picture, we developed Table 12-3. Table 12-3 shows the total registration results along with the irrigation (Table 12-1) registrations we were able to split out and the animal (Table 12-2) registrations we were able to split out of the earlier analyses. In addition the register water shown for each county is the total registered water in each county (all registered water is included even the registrations with no monthly breakdown that were rejected in the earlier irrigation and animal analysis). The headings in Table 12-3 are total "water needed" for irrigation and animal needs combined, total "irrig + animal registered", which is the sum of columns 3 from Tables 12-1 and 12-2, total "water registered", which is the total water registered including the registrants that gave no monthly breakdown, and "Unregistered water", which is the subtraction of column5 from column 3 (the "total water needed" for both irrigated and animal agriculture obtained from our evaluation and presented in Chapters 6 and 9 minus the "total water registered" for each county. The right-hand column of Table 12-3 paints a slightly different picture. Since many of the final column values are negative () it indicates that in many counties more agricultural water was registered than is most probably going to be used by the farmers in these counties. No monthly

breakdown was given by these registrants, so we had no way of including these data in our analysis relative to irrigation or animals, but there has apparently been very good response to registration. In fact, the state totals show the total water needed for agriculture in 2002 at about 28,000 MG and the total registered water just under 52,000 MG.

# Table C-4. Irrigated acreages in 2030.

# APPENDIX D

# Current and Future Q<sub>7-10</sub> Water Volumes Needed to Provide Irrigation in 2002, 2010, 2020, and 2030

Appendix D is laid out in two sections.

**Section 1** shows the maximum daily  $(Q_{7-10})$  volume of water (in MGD) that was used in 2002 or is predicted to be used in 2010, 2020, and 2030 for irrigating each of the crops.

Section 2 shows the top ten counties for each of the major irrigated crops for each of the years 2002, 2010, 2020, and 2030.

# Section 1

# Shows the maximum daily volume of water (in MGD) that was used in 2002 or is predicted to be used in 2010, 2020, and 2030 for irrigating each of the crops.

Table D-8. Top ten counties for each major crop in 2030.

# APPENDIX E

# Current and Future Annual Water Volumes Needed to Provide Irrigation in 2002, 2010, 2020, and 2030

Appendix E is laid out in two sections.

Section 1 shows the volume of water (in MG) that was used in 2002 or is predicted to be used in 2010, 2020, and 2030 for irrigating each of the crops.

**Section 2** shows the top ten counties for each of the major irrigated crops for each of the years 2002, 2010, 2020, and 2030.

### Section 1

# Shows the volume of water (in acre-feet) that was used in 2002 or is predicted to be used in 2010, 2020, and 2030 for irrigating each of the crops.

 Table E-8. Top ten counties for each major crop in 2030.

### APPENDIX F

# Current and Future Animal Populations and Water Volumes Needed to Support Animal Agriculture in 2002, 2010, 2020, and 2030.....

Appendix F is laid out in three sections.

**Section 1** shows the current animal populations or the predicted animal populations in each county in 2002, 2010, 2020, and 2030 identified by each species for which population numbers were available.

Section 2 shows the volume of water (in MGD) that was used in 2002 or is predicted to be used in 2010, 2020, and 2030 for supplying each species.

**Section 3** shows the top ten counties for each of the major animal species for each of the years 2002, 2010, 2020, and 2030.

### Section 1

## Shows the current animal populations or the predicted animal populations in each county in 2002, 2010, 2020, and 2030 identified by each species for which population numbers were available.
